8th CAIDA/WIDE workshop – July, 2007
Introduction

• Any DNS operator, specially those running an anycast infrastructure, need to know if the load is well balanced between the nodes and which would be a right place to put a new node.

• The first question could be answered comparing simple query load graphs, but the second requires some work.

• The following visualization is intended to help to answer that question.
Query load per topological origin

- Anycast is based on routing protocols (mainly BGP).
- The selection of the placement for a new node should be ruled by the origin of the queries received, either by country or by AS.
- There is no strict correlation between geography and AS topology
  – One AS could span over several countries.
Query load per topological origin

• Methodology
  – Using packet traces from every node in the .CL anycast cloud and the BGP tables available on those nodes, we counted the number of queries from each origin AS.
  – Also prepared a topology map
  – The map shows AS relations, number of queries originated from those AS and their relation with the AS holding the anycast node.
  – In some cases, there are too many origin AS to fit into the plot. In those cases, only the set of AS representing >70% of the total query load are plotted.
Query load per topological origin
Query load per topological origin
Geographic map

- There are several tools to represent the query load aggregated by “geography”
  - Like “root servers influence map” by Bradley Huffaker from CAIDA
- This visualization provides a different angle.
  - Each country is colored by the number of queries originated from there.
  - It is a vector-based format (not raster). Does not loose resolution when zoomed-in.
Geographic map

Queries per minute aggregated by country
seen at .CL anycast cloud
from 2007-04-18 11:00 to 2007-04-18 17:00 (CLT)
Geographic animated map

• The next step was prepare an animation showing the evolution of the traffic along the day.
  – Idea inspired by cuttlefish tool from CAIDA

• Methodology
  – One hour traces using dnscap
  – Generate aggregated traffic by source address using CoralReef
  – Map address to geography using NetAcuity
  – Aggregate the query load by country
  – Plot the aggregated data using the home-grown tool.
Geographic animated map

- Snapshot of the animated map
Geographic animated map

• Future work
  – Pack the tool
  – Improve documentation
  – Release it to the public
